Scanning Near-field Optical Microscopy

Optical Imaging and Spectroscopy on the Nanometer Scale

SNOM applications in the following areas are presented:

- Laser emission
- Optical fibers
- Optical micro-devices
- Plasmonics
- Photonic crystals and waveguides
- Photovoltaics
- Polymers
Scanning near-field optical microscopy (SNOM) enables studying a sample’s optical properties with resolution far beyond the diffraction limit. Sample fluorescence, light emission, transmission, scattering etc. can be mapped with the spatial resolution down to tens of nanometers.

Two main approaches to the near-field microscopy exist: (i) aperture type SNOM and (ii) apertureless techniques.

In the first case, a subwavelength size aperture on a scanning tip is used as an optical probe. This is usually an opening in a metal coating of either an optical fiber tip or of a cantilever. Spatial resolution in the aperture type SNOM is, in general, determined by the aperture diameter.

Apertureless techniques are based on the near-field optical phenomena as well, but do not require passing the light through an aperture. Apertureless/Scattering SNOM, Tip Enhanced Raman/Fluorescence, STM Light Emission and others can be mentioned in this regard.

SNOM techniques are widely used in nanophotonics (plasmonics, photonic crystals & waveguides etc.), laser technology, optical micro-devices, material science.

NT-MDT SNOM Features:

- **All major types of SNOM probes and measuring modes supported**
  Apertured cantilevers, different types and shapes of apertured optical fibers and even sharpened metal wires can be used as SNOM probes. Major SNOM measuring modes are: Transmission, Collection and Reflection. Signals measured: laser intensity, fluorescence intensity and full emission spectra.

- **Apertureless techniques: Scattering SNOM, Tip Enhanced Raman/Fluorescence and others**
  In general, all types of optical, mechanical, and electrical interactions between the probe, sample and incident light source can be studied by NT-MDT SNOM setup.

- **Scanning by sample and/or by probe**
  Depending on the type of sample and measurement, it is important to have the option to scan either by the sample or by the probe to obtain SNOM images.

- **Environmental control (temperature, gases, humidity, liquid and external magnetic field)**
  Temperature control and air flow isolation are the key issues for measurements stability. Sample heating and controlled gas atmosphere removes the residual water layer on the sample (this is usually present in ambient conditions and affects any surface measurements). This prevents unwanted chemical reactions on the surface and other measurement artifacts.

- **Extended spectral region (UV – Vis – IR)**
  Standard supported wavelength range is 400 – 1700 nm. Customized solutions for wider ranges are possible.

- **Easy integration with AFM & confocal Raman microscopy**
  Universal NT-MDT NTEGRA SPM base allows one to switch easily between any types of AFM/STM/SNOM measuring heads and environmental cells. The setup can be further integrated with a Raman spectrometer to provide simultaneous AFM/Confocal Raman & fluorescence imaging in addition to SNOM.

Optical Imaging and Spectroscopy on the Nanometer Scale

SNOM Imaging for Laser Studies

Study of Laser Emission Properties

SNOM can be effectively used to study laser emission properties. Both near-field (right at the laser facet) and far-field (at a certain distance from the facet) emission patterns can be obtained with high spatial resolution (<50 nm). Both emission intensity and full emission spectrum can be recorded during a 2D or 3D optical scan.

![Fig. 1](a) Side view SEM image of a very-small-aperture-laser (VSAL) facet with an annular aperture (left) and a circular aperture (right). (b) Intensity distribution of the light emission (at 650 nm) detected at the surface of the VSAL facet.

Focusing behavior of a binary phase micro-Fresnel zone plate (FZP) fabricated using focused ion beam milling on a glass substrate is studied by SNOM. It is found that an asymmetric spot with subwavelength beam width and elongated depth of focus can be obtained from the phase micro-FZP. The measurements are consistent with calculation results.

---

**Characterization of a Micro-focusing Plasmonic Device**

Focusing behavior of Au based focusing plasmonic device is characterized by SNOM. The experimental results show a significant focusing effect in agreement with the simulation results.

**Data from:** Dr. Fenghuan Hao, Dr. Rui Wang and Dr. Jia Wang, OPTICS EXPRESS Vol. 18, No. 3, 15741-15746 (2010)
Light Spot Narrowing by an asymmetric Axicon

Diffraction of a Gaussian beam by axicons is studied by SNOM. Binary diffraction axicons with the period close to the light wavelength are formed by electron beam lithography on a quartz substrate. Different axicon geometries are studied. It is shown experimentally that asymmetric microaxicon can reduce the spot size of central light beam along polarization direction in a near zone of diffraction – overcoming the diffraction limit.

![Light Spot Narrowing by an asymmetric Axicon](image)

**Fig. 7.** (a) SEM image of the central part of a spiral axicon. (b) The diffracted light intensity distribution detected by SNOM in close proximity to the surface. (c) SNOM intensity distribution taken at ~500 nm from the surface. The central part of the beam at this plane is compressed in a light polarization direction (vertical) and has size less than optical limit. (d) Series of intensity distribution: the height of a scanning plane was varied from 500 nm to 1500 nm.

Focusing of a Radially Polarized Beam by a Solid Immersion Lens

Radially polarized beam focused by a solid immersion lens (SIL) is studied by SNOM. It delivers a laser spot beyond the diffraction limit demonstrating better focusing properties than a common linearly polarized beam.

![Focusing of a Radially Polarized Beam by a Solid Immersion Lens](image)

**Fig. 8.** Measured focus spot by a solid immersion lens with incident annular radially polarized beam, i.e., evanescent Bessel beam: (a) intensity distribution on the SIL bottom surface; (b) intensity along the X direction. The FWHM is 230 nm; (c) intensity along the Y direction. The FWHM is 180 nm. Size of the spot in both X and Y direction are considerably less than diffraction limit.

Color Separation in the Fresnel Diffraction Region of Rectangular Grating

Color separation of the incident light in the Fresnel diffraction region is a novel function of high-density dielectric rectangular gratings. Light of different wavelengths has different diffraction periods in the Z direction. For example, at 4.2 μm distance from the surface, position of intensity maximum for red excitation laser corresponds to position of intensity minimum for blue excitation laser — a spatial light separation occurs.

![Diagram](image)

**Fig. 9.** (a) Schematics of the fabricated grating. The period of the grating is \(1.5 \lambda (\lambda = 633 \text{ nm})\), and the duty cycle is 0.5. (b), (c) Calculated diffraction distributions for different incident wavelengths: 488 nm and 633 nm correspondingly. (d) The shear-force topography of the grating. Experimental results scanned by SNOM at \(z = 4.2 \mu m\): (e) the field distribution with the incident laser wavelength 633 nm (bottom half) and 488 nm (top half), and (f) the intensity distribution at the same cross section for different wavelength of the incident laser.

**Data from:** Yue Fang, Qiaofeng Tan, Mingqian Zhang and Guofan Jin, APPLIED OPTICS, Vol. 51, No. 12, 2172-2177 (2012)

SNOM for Plasmonics

SNOM is traditionally used to examine the Surface Plasmon Polaritons (SPP) behavior with high spatial resolution in all three dimensions (XYZ).

**Plasmonic Fan-Out**

SPP behavior is often studied in relation to conventional optical devices such as beam splitters and waveguides. The work conducted by Wang et al. (Fig. 10) realizes traditional fan-out optical arrangement in a plasmonic device. An optical fan-out element typically splits a single wave into plane waves by using gratings and lenses to generate an array of light spots.

A plasmonic fan-out array is generated by the structure shown in Fig. 10 (a, b). The device is produced using arrays of slits on a metal film, the slits being of less than the wavelength dimensions of the initial light. The structure consists of a 100 nm silver film deposited on a quartz substrate. The slit arrays are cut into the silver film by electron beam lithography (EBL) at a width of 265 nm to generate the highest surface plasmon response.

The near field characteristics of the SPP pattern are investigated by SNOM with an aluminium coated fiber tip. The results of the imaging analysis are shown in Fig. 10 (c).
Scanning Near-field Optical Microscopy (SNOM)
Optical Imaging and Spectroscopy on the Nanometer Scale

**Fig. 10.** (a) Subwavelength slit arrays are used to generate SPP waves propagating along the metal surface and four perpendicular counter-propagating SPP waves interfered each other to form the localized plasmonic dots array. (b) SEM image of subwavelength slit arrays structure. (c) 2D Near field image of electrical field distribution for diagonal polarization direction. Inset is the SPP field intensity distribution of the structure’s centre area. The white arrow indicates the incident polarization direction. Excitation laser wavelength is 633 nm.

**Generation of Plasmonic Moiré Fringes Using Phase-engineered Optical Vortex Beam**

The work demonstrates the dynamic generation of two dimensional (2D) plasmonic Moiré fringes resulting from the overlapping of two Surface Plasmon Polaritons (SPP) standing waves with an angular misalignment. The SPP waves are excited by an optical vortex (OV) beam with different topological charges ($l = \pm 6$). The sign of $l$ determines handedness of the helical wave front. Due to their unique phase properties, OV beams provide a natural and simple phase modulation method to effectively and dynamically manipulate SPPs.

**Fig. 11.** (a) SEM image of four metallic gratings to generate plasmonic Moiré fringes. Black arrow shows the polarization direction of incident optical vortex beam. Red and blue arrows show the propagation direction of SPP excited by positive and negative topological charge optical vortex beams, respectively. (b) SNOM measured Moiré fringes resulting from overlapping of the two SPP standing waves.

SNOM for Photonic Crystals

**Light Propagation in a Photonic Crystal Waveguide**

Aperture-SNOM in collection mode is used to correlate the electromagnetic field distribution with the surface topography of the photonic crystal. The optical near-field confined above the sample surface is collected by a SNOM tip, placed several nanometers above the sample surface.

**Fig. 14.** Light propagation in a one-line-defect photonic crystal (PhC) waveguide patterned into a 450 nm thick free-standing lithium niobate membrane. SNOM topography (a) and optical near-field (b) images recorded above the surface of the PhC waveguide. The Bloch wave vectors of the PhC waveguide can be retrieved from optical near-field images. 
*Data from:* R. Geiss, S. Diziain, N. Janunts, *APPLIED PHYSICS LETTERS* 97, 131109 (2010)

**Analysis of Slow Bloch Modes in a Photonic Crystal**

The photonic crystal is prepared by drilling a honeycomb lattice of air holes in the InP slab using e-beam lithography followed by reactive ion etching. Near-field optical microscopy is used to visualize the evanescent component of the mode with a spatial resolution below the diffraction limit.

**Fig. 15.** (a) Shear-force topographic image. (b) Optical near-field image at 1611 nm (2.5×2.5 μm), circles indicate holes positions of the 2D-Photonic crystal. Doughnut-shaped monopolar modes in each unit cell are observed, having the inner and outer radiiuses 70 nm and 310 nm correspondingly. (c) Simulated electrical field intensity at the surface of the photonic crystal. 
### SNOM for Polymers

**Perylene Embedded in Polyfluorene**

Perylene (a small-molecular organic semiconductor) was embedded in Polyfluorene (PFO) polymer organic semiconductor thin film forming a rhombus structure. SNOM transmission spectroscopy scheme was used to study the optical properties of the structure. It is known that fluorescence properties of perylene nanosheets directly relate to their crystal structures. For  \( \beta \)-phase rhombus perylene, the fluorescence peak is around 620 nm, which can be clearly observed from fluorescent spectra along the section on the SNOM image. Excitation laser wavelength was 473 nm.

**Fig. 17.** (a) AFM image of Perylene embedded in PFO. (b) SNOM transmission image. (c) Fluorescent spectra for 10 points of section from the SNOM image.

*Data from:* P. Dorozhkin, E. Kuznetsov, S. Timofeev; NT-MDT.

---

### SNOM for Photovoltaics

**Localized SNOM Excitation for Solar Cell Studies**

SNOM is used for localized optical excitation of a monocrystalline silicon solar cell. Topography, local surface reflection and localized photoresponse of the cell are simultaneously mapped while scanning with the SNOM probe. This allows characterizing near-surface defects and other optoelectrical properties of the cell with high spatial resolution and correlating them with the surface topography.

*Fig. 16.* (a) Scheme of setup. (b) Overlay of sample topography (3D surface profile) and localized photo-induced current (color scale).
